

|  |   |  |  |  |  |
|--|---|--|--|--|--|
| <b>Normalization</b>                     | is a process of organizing data to minimize data redundancy. Which in turn ensures data consistency.  |  |  | <b>Advn. Of RDBMS</b>  | <ul style="list-style-type: none"> <li>Controlling Redundancy.</li> <li>Integrity can be enforced.</li> <li>Inconsistency can be avoided.</li> <li>Data can be shared.</li> <li>Standard can be enforced</li> </ul>  |
| <b>1NF</b>                               | Identity each record uniquely using the primary key.  |  |  | <b>JPA</b>   | Mapping between database tables and java objects called ORM. JPA provides an ORM facility for managing relational tables in Java applications.   |
| <b>2NF</b>                               | move redundant data to separate table. creates a relationship between these tables using foreign keys.  |  |  | <b>EntityManager</b>   | provides the operations from & to the database, e.g. find objects, persists them, remove objects from the db, etc.   |
| <b>3NF</b>                               | doesn't contain attributes which are partially dependent upon primary key.  |  |  | <b>Annotations</b>   | <b>1. Entity:</b> Used with model classes to specify that they are entity beans.<br><b>2. Table:</b> Used with entity beans to define the corresponding table name in database.<br><b>3. Access:</b> define the access type, either field or prop.<br><b>4. Id:</b> Used to define the primary key in the entity bean.<br><b>5. EmbeddedId:</b> define composite pk in the entity bean.<br><b>6. Column:</b> Used to define the column name in db table.<br><b>7. GeneratedValue:</b> strategy to be used for generation of pk. Used in conjunction with GenerationType enum.<br><b>8. OneToOne:</b> define the mapping b/w two entities., one-to-one, OneToMany, ManyToOne and ManyToMany<br><b>9. Cascade:</b> define the cascading b/w two entities, used with mappings. It works in conjunction with CascadeType<br><b>10. PrimaryKeyJoinColumn:</b> define the property for foreign key. Used with GenericGenerator and Parameter |
| <b>Adv Of Hibernate</b>                  | 1. Removes boilerplate code that comes with JDBC.<br>2. supports inheritance, associations and collections.<br>3. implicitly provides transaction management<br>4. HQL is more object oriented.<br>5. supports caching that is better for performance.<br>6. provide option where we can create db tables too<br>7. Supports JPA annotations. |  |  |  |  |
| <b>Important Interfaces of Hibernate</b> | 1. SessionFactory (org.hibernate.SessionFactory)<br>2. Session (org.hibernate.Session)<br>3. Transaction (org.hibernate.Transaction)  |  |  | <b>Hibernate Config file</b>   | Hibernate configuration file contains database specific configurations and used to initialize SessionFactory. database credentials or JNDI resource or dialect info.   |
| <b>Session Factory</b>                   | SessionFactory is an immutable thread-safe cache of compiled mappings for a single database. SessionFactory instance is used to get the Session objects for database operations.  |  |  | <b>Hibernate mappings file</b>   | Hibernate mapping file is used to define the entity bean fields and database table column mappings.  |
| <b>Session</b>                           | Session is a single-threaded, short-lived object representing a conversation between the application and the persistent store.  |  |  | <b>Get vs load</b>   | 1. load() is better because it support lazy loading.<br>2. load() throws exception when data is not found<br>3. use get() to make sure data exists in the db.  |
| <b>Transaction</b>                       | Transaction is a single-threaded, short-lived object used by the application to specify atomic units of work.   |  |  | <b>Transient:</b> an obj never persisted/associated with any session.  | <b>Persistent:</b> an obj associated with uniq sess.<br><b>Detached:</b> an obj prev persistent but not assoc. with any sess.  |
| <b>Named Query</b>                       | Hibernate provides Named Query that we can define at a central location and use them anywhere in the code. @NamedQuery and @NamedNativeQuery.   |  |  | <b>Save:</b> save with no transaction. Results in data inconsistency.  | <b>Persist:</b> Save with transaction.<br><b>SaveOrUpdate:</b> just like the name depends on the data.   |
| <b>Hiber. Design patterns</b>            | Domain model pattern, Data mapper, Proxy pattern, Factory pattern   |  |  | <b>Optimistic Locking</b> is is a strategy where you read a record, take note of a version number (other methods to do this involve dates, timestamps or checksums/hashes) and check that the version hasn't changed before you write the record back. |  |
| <b>Hiber Collec's</b>                    | Bag, Set, List, Array, Map  |  |  | <b>Pessimistic Locking</b> is when you lock the record for your exclusive use until you have finished with it.   |  |
